What is credit risk?

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

What is credit risk?

Citation from McNeil, Frey und Embrechts (2005):

Credit risk is the risk that the value of a portfolio changes due to unexpected changes in the credit quality of issuers or trading partners. This subsumes both losses due to defaults and losses caused by changes in credit quality such as the downgrading of a counterparty in an internal or external rating system.

This subsumes both losses due to defaults and losses caused by changes in credit quality such as the downgrading of a counterparty in an internal or external rating system.

Examples of finance instruments affected by credit risk

- bond portfolios
- OTC ("over the counter") transactions
- trades with credit derivatives

Let P be a portfolio of n risky bonds of nominal value L_i , i = 1, 2, ..., n, respectively, set up at time T_0 .

 p_i : the probability that (the issuer of) bond *i* defaults until time *T*, $T > T_0$

 $\lambda_i \in [0,1]$: "recovery rate" of bond i

 $1 - \lambda_i$: percentage of lost value of bond *i* in case of default until time T

The loss given default for bond *i* at time T: $LGD_i = (1 - \lambda_i)L_i$

Let P be a portfolio of n risky bonds of nominal value L_i , i = 1, 2, ..., n, respectively, set up at time T_0 .

 p_i : the probability that (the issuer of) bond *i* defaults until time T, $T > T_0$

 $\lambda_i \in [0,1]$: "recovery rate" of bond i

 $1 - \lambda_i$: percentage of lost value of bond *i* in case of default until time T

The loss given default for bond *i* at time T: $LGD_i = (1 - \lambda_i)L_i$

Model the default of bond i until time T by a Bernoulli distributed r.v. X_i with with $p_i = P(X_i = 1)$:

 $X_i = \begin{cases} 1 & \text{bond } i \text{ defaults} \\ 0 & \text{otherwise} \end{cases}$

Let P be a portfolio of n risky bonds of nominal value L_i , i = 1, 2, ..., n, respectively, set up at time T_0 .

 \textit{p}_i : the probability that (the issuer of) bond i defaults until time T, $T > T_0$

 $\lambda_i \in [0,1]$: "recovery rate" of bond i

 $1 - \lambda_i$: percentage of lost value of bond *i* in case of default until time T

The loss given default for bond *i* at time T: $LGD_i = (1 - \lambda_i)L_i$

Model the default of bond i until time T by a Bernoulli distributed r.v. X_i with with $p_i = P(X_i = 1)$:

 $X_i = \begin{cases} 1 & \text{bond } i \text{ defaults} \\ 0 & \text{otherwise} \end{cases}$

Total loss at time T: $L = \sum_{i=1}^{n} X_i \cdot LGD_i = \sum_{i=1}^{n} X_i(1 - \lambda_i)L_i$.

Let P be a portfolio of n risky bonds of nominal value L_i , i = 1, 2, ..., n, respectively, set up at time T_0 .

 \textit{p}_i : the probability that (the issuer of) bond i defaults until time T, $T > T_0$

 $\lambda_i \in [0,1]$: "recovery rate" of bond i

 $1 - \lambda_i$: percentage of lost value of bond *i* in case of default until time T

The loss given default for bond *i* at time T: $LGD_i = (1 - \lambda_i)L_i$

Model the default of bond i until time T by a Bernoulli distributed r.v. X_i with with $p_i = P(X_i = 1)$:

 $X_i = \begin{cases} 1 & \text{bond } i \text{ defaults} \\ 0 & \text{otherwise} \end{cases}$

Total loss at time T: $L = \sum_{i=1}^{n} X_i \cdot LGD_i = \sum_{i=1}^{n} X_i (1 - \lambda_i)L_i$.

L is a r.v. and its distribution depends from the c.d.f. of $(X_1, \ldots, X_n, \lambda_1, \ldots, \lambda_n)^T$ ab.

 $S = (S_1, S_2, ..., S_n)$, $S_i \in \{0, 1, ..., m\}$, is a status vector representing the category assignment; $S_i = j \in \{1, 2, ..., m\}$ means that obligor *i* belongs to category *j* (e.g. categories could be the rating classes). $S_i = 0$ corresponds to default.

Then we have
$$X_i = \left\{ egin{array}{cc} 0 & S_i
eq 0 \ 1 & S_i = 0 \end{array}
ight.$$

 $S = (S_1, S_2, \dots, S_n)^T$ is modelled by means of latent variables $Y = (Y_1, Y_2, \dots, Y_n)^T$, e.g. Y_i could be the value of the assets of obligor i

 $S = (S_1, S_2, ..., S_n)^T$ is modelled by means of latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$, e.g. Y_i could be the value of the assets of obligor *i* (firm value models).

(日) (日) (日) (日) (日) (日) (日) (日)

 $S = (S_1, S_2, ..., S_n)^T$ is modelled by means of latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$, e.g. Y_i could be the value of the assets of obligor *i* (firm value models).

Let d_{ij} , i = 1, 2, ..., n, j = 0, 1, ..., m + 1 be threshold values such that $d_{i,0} = -\infty$ und $d_{i,m+1} = \infty$ and $S_i = j \iff Y_i \in (d_{i,j}, d_{i,j+1}]$.

 $S = (S_1, S_2, ..., S_n)^T$ is modelled by means of latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$, e.g. Y_i could be the value of the assets of obligor *i* (firm value models).

Let d_{ij} , i = 1, 2, ..., n, j = 0, 1, ..., m + 1 be threshold values such that $d_{i,0} = -\infty$ und $d_{i,m+1} = \infty$ and $S_i = j \iff Y_i \in (d_{i,j}, d_{i,j+1}]$.

Let F_i be the distribution function of Y_i . The probability of default for obligor *i* is $p_i = F_i(d_{i,1})$.

 $S = (S_1, S_2, ..., S_n)^T$ is modelled by means of latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$, e.g. Y_i could be the value of the assets of obligor *i* (firm value models).

Let d_{ij} , i = 1, 2, ..., n, j = 0, 1, ..., m + 1 be threshold values such that $d_{i,0} = -\infty$ und $d_{i,m+1} = \infty$ and $S_i = j \iff Y_i \in (d_{i,j}, d_{i,j+1}]$.

Let F_i be the distribution function of Y_i . The probability of default for obligor *i* is $p_i = F_i(d_{i,1})$.

The probability that the fisrt k obligors default:

$$p_{1,2,\ldots,k} := P(Y_1 \leq d_{1,1}, Y_2 \leq d_{2,1}, \ldots, Y_k \leq d_{k,1})$$

 $= C(F_1(d_{1,1}), F_2(d_{2,1}), \dots, F_k(d_{k,1}), 1, 1, \dots, 1) = C(p_1, p_2, \dots, p_k, 1, \dots, 1)$ Thus the totalt defalut probability depends essentially on the copula C of (Y_1, Y_2, \dots, Y_n) .

The status variables $S = (S_1, S_2, \dots, S_n)$ can only take two values 0 or 1, i.e. m = 1.

The status variables $S = (S_1, S_2, ..., S_n)$ can only take two values 0 or 1, i.e. m = 1.

The latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$ depend on the value of the assets of the obligors as follows.

Merton's model

The balance sheet of each firm consists of assets and liabilities. The latter are devided in debt and equities.

The status variables $S = (S_1, S_2, ..., S_n)$ can only take two values 0 or 1, i.e. m = 1.

The latent variables $Y = (Y_1, Y_2, ..., Y_n)^T$ depend on the value of the assets of the obligors as follows.

Merton's model

The balance sheet of each firm consists of assets and liabilities. The latter are devided in debt and equities.

Notations:

 $V_{A,i}(T)$: value of assets of firm *i* at time point T $K_i := K_i(T)$: value of the debt of firm *i* at time point T $V_{E,i}(T)$: value of equity of firm *i* at time point T

Assumption: future asset value is modelled by a geometric Brownian motion

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},\$$

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}$ is the volatility and $(W_i(t): 0 \le t \le T)$ is a standard Brownian motion (or equivalently a Wiener process).

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}$ is the volatility and $(W_i(t): 0 \le t \le T)$ is a standard Brownian motion (or equivalently a Wiener process). Hence $(W_i(T) - W_i(t)) \sim N(0, T - t)$ and $\ln V_{A,i}(T) \sim N(\mu, \sigma^2)$ with

(日) (日) (日) (日) (日) (日) (日) (日)

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}$ is the volatility and $(W_i(t): 0 \le t \le T)$ is a standard Brownian motion (or equivalently a Wiener process). Hence $(W_i(T) - W_i(t)) \sim N(0, T - t)$ and $\ln V_{A,i}(T) \sim N(\mu, \sigma^2)$ with $\mu = \ln V_{A,i}(t) + \left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T - t)$ and $\sigma^2 = \sigma_{A,i}^2(T - t)$.
$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}$ is the volatility and $(W_i(t): 0 \le t \le T)$ is a standard Brownian motion (or equivalently a Wiener process). Hence $(W_i(T) - W_i(t)) \sim N(0, T - t)$ and $\ln V_{A,i}(T) \sim N(\mu, \sigma^2)$ with $\mu = \ln V_{A,i}(t) + \left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T - t)$ and $\sigma^2 = \sigma_{A,i}^2(T - t)$. Further $X_i = I_{(-\infty,K_i)}(V_{A,i}(T))$ holds.

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

$$\begin{split} & \mu_{A,i} \text{ is the drift, } \sigma_{A,i} \text{ is the volatility and } (W_i(t): 0 \leq t \leq T) \text{ is a} \\ & \text{standard Brownian motion (or equivalently a Wiener process).} \\ & \text{Hence } (W_i(T) - W_i(t)) \sim \mathcal{N}(0, T - t) \text{ and } \ln V_{A,i}(T) \sim \mathcal{N}(\mu, \sigma^2) \text{ with} \\ & \mu = \ln V_{A,i}(t) + \left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right) (T - t) \text{ and } \sigma^2 = \sigma_{A,i}^2 (T - t). \\ & \text{Further } X_i = I_{(-\infty, K_i)}(V_{A,i}(T)) \text{ holds.} \\ & \text{Set } Y_i = \frac{W_i(T) - W_i(t)}{\sqrt{T - t}} \sim \mathcal{N}(0, 1). \end{split}$$

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

$$\begin{split} & \mu_{A,i} \text{ is the drift, } \sigma_{A,i} \text{ is the volatility and } (W_i(t): 0 \leq t \leq T) \text{ is a} \\ & \text{standard Brownian motion (or equivalently a Wiener process).} \\ & \text{Hence } (W_i(T) - W_i(t)) \sim N(0, T - t) \text{ and } \ln V_{A,i}(T) \sim N(\mu, \sigma^2) \text{ with} \\ & \mu = \ln V_{A,i}(t) + \left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right) (T - t) \text{ and } \sigma^2 = \sigma_{A,i}^2 (T - t). \\ & \text{Further } X_i = I_{(-\infty,K_i)}(V_{A,i}(T)) \text{ holds.} \\ & \text{Set } Y_i = \frac{W_i(T) - W_i(t)}{\sqrt{T - t}} \sim N(0, 1). \\ & \text{Then we get: } X_i = I_{(-\infty,K_i)}(V_{A,i}(T)) = I_{(-\infty,-DD_i)}(Y_i) \text{ where} \\ & DD_i = \frac{\ln V_{A,i}(t) - \ln K_i + (\mu_{A,i} - \frac{\sigma_{A,i}^2}{2})(T - t)}{\sigma_{A,i}\sqrt{T - t}} \end{split}$$

$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sigma_{A,i}\left(W_i(T) - W_i(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}$ is the volatility and $(W_i(t): 0 \le t \le T)$ is a standard Brownian motion (or equivalently a Wiener process). Hence $(W_i(T) - W_i(t)) \sim N(0, T-t)$ and $\ln V_{A,i}(T) \sim N(\mu, \sigma^2)$ with $\mu = \ln V_{A,i}(t) + \left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) \text{ and } \sigma^2 = \sigma_{A,i}^2(T-t).$ Further $X_i = I_{(-\infty,K_i)}(V_{A,i}(T))$ holds. Set $Y_i = \frac{W_i(T) - W_i(t)}{\sqrt{T-t}} \sim N(0, 1).$ Then we get: $X_i = I_{(-\infty,K_i)}(V_{A,i}(T)) = I_{(-\infty,-DD_i)}(Y_i)$ where $DD_{i} = \frac{\ln V_{A,i}(t) - \ln K_{i} + (\mu_{A,i} - \frac{\sigma_{A,i}^{2}}{2})(T-t)}{\sigma_{A,i}\sqrt{T-t}}$ DD; is called *distance-to-default*.

The KMV model (contd.) Computation of the "distance to default"

(ロ)、(型)、(E)、(E)、 E) の(の)

Computation of the "distance to default"

 V_A , i(t), $\mu_{A,i}$ and $\sigma_{A,i}$ are needed.

Computation of the "distance to default"

 $V_A, i(t), \mu_{A,i}$ and $\sigma_{A,i}$ are needed. Difficulty: $V_{A,i}(t)$ can not be observed directly.

Computation of the "distance to default"

 V_A , i(t), $\mu_{A,i}$ and $\sigma_{A,i}$ are needed.

Difficulty: $V_{A,i}(t)$ can not be observed directly.

However $V_{E,i}(t)$ can be observed by looking at the market stock prices.

Computation of the "distance to default"

 V_A , i(t), $\mu_{A,i}$ and $\sigma_{A,i}$ are needed.

Difficulty: $V_{A,i}(t)$ can not be observed directly.

However $V_{E,i}(t)$ can be observed by looking at the market stock prices.

KMVs viewpoint: the equity holders have the right, but not the obligation, to pay off the holders of the other liabilities and take over the remaining assets of the firm.

Computation of the "distance to default"

 V_A , i(t), $\mu_{A,i}$ and $\sigma_{A,i}$ are needed.

Difficulty: $V_{A,i}(t)$ can not be observed directly.

However $V_{E,i}(t)$ can be observed by looking at the market stock prices.

KMVs viewpoint: the equity holders have the right, but not the obligation, to pay off the holders of the other liabilities and take over the remaining assets of the firm.

This can be seen as a call option on the firms assets with a strike price equal to the book value of the firms liabilities.

$$V_{E,i}(t) = C(V_{A,i}(t), r, \sigma_{A,i})$$

$$\sigma_{E,i} = g(V_{A,i}(t), \sigma_{A,i}, r)$$

The KMV model also postulates

 $\sigma_{E,i} = g(V_{A,i}(t), \sigma_{A,i}, r)$, where g is some suitably selected proprietary function.

 $V_{E,i}(t)$ and $\sigma_{E,i}$ are estimated based on historical data and the system of equalities below is solved w.r.t. $V_{A,i}(t)$ and $\sigma_{A,i}$:

$$V_{E,i}(t) = C(V_{A,i}(t), r, \sigma_{A,i})$$

$$\sigma_{E,i} = g(V_{A,i}(t), \sigma_{A,i}, r)$$

The values obtained for $V_{A,i}(t)$ and $\sigma_{A,i}$ are used to compute DD_i :

$$DD_{i} = \frac{\ln V_{A,i}(t) - \ln K_{i} + (\mu_{A,i} - \frac{\sigma_{A,i}^{2}}{2})(T-t)}{\sigma_{A,i}\sqrt{T-t}}$$

The KMV model also postulates

 $\sigma_{E,i} = g(V_{A,i}(t), \sigma_{A,i}, r)$, where g is some suitably selected proprietary function.

 $V_{E,i}(t)$ and $\sigma_{E,i}$ are estimated based on historical data and the system of equalities below is solved w.r.t. $V_{A,i}(t)$ and $\sigma_{A,i}$:

$$V_{E,i}(t) = C(V_{A,i}(t), r, \sigma_{A,i})$$

$$\sigma_{E,i} = g(V_{A,i}(t), \sigma_{A,i}, r)$$

The values obtained for $V_{A,i}(t)$ and $\sigma_{A,i}$ are used to compute DD_i :

$$DD_{i} = \frac{\ln V_{A,i}(t) - \ln K_{i} + (\mu_{A,i} - \frac{\sigma_{A,i}^{2}}{2})(T-t)}{\sigma_{A,i}\sqrt{T-t}}$$

Then $P(V_{A,i}(T) < K_i) = P(Y_i < -DD_i)$ and in the general setup of the latent variable model with m = 1 we have $d_{i1} = -DD_i$.

<□ > < @ > < E > < E > E のQ @

In the KMV model the default probability is not computed by setting $p_i := P(Y_i < -DD_i)$.

In the KMV model the default probability is not computed by setting $p_i := P(Y_i < -DD_i)$.

Alternative: historical data are used to identify companies which at some stage in their history had the same distance to default DD_i .

In the KMV model the default probability is not computed by setting $p_i := P(Y_i < -DD_i)$.

Alternative: historical data are used to identify companies which at some stage in their history had the same distance to default DD_i .

Then the observed default frequency is used as an estimator for the default probability p_i .

In the KMV model the default probability is not computed by setting $p_i := P(Y_i < -DD_i)$.

Alternative: historical data are used to identify companies which at some stage in their history had the same distance to default DD_i .

Then the observed default frequency is used as an estimator for the default probability p_i . This estimator is called *expected default frequency*, *(EDF)*.

In the KMV model the default probability is not computed by setting $p_i := P(Y_i < -DD_i)$.

Alternative: historical data are used to identify companies which at some stage in their history had the same distance to default DD_i .

Then the observed default frequency is used as an estimator for the default probability p_i . This estimator is called *expected default frequency*, *(EDF)*.

Summary of the univariate KMV model to compute the default probability of a company:

- Estimate the asset value $V_{A,i}$ and the volatility $\sigma_{A,i}$ by using observations of the market value and the volatility of equity $V_{E,i}$, $\sigma_{E,i}$, the book of liabilities K_i , and by solving the system of equations above.
- Compute the distance-to-default DD_i by means of the corresponding formula.
- Estimate the default probability p_i in terms of the empirical distribution which relates the distance to default with the expected default frequency.

Let Wj(t) be independent standard Brownian motions for $0 \le t \le T$, $j = 1, 2, \ldots, m$.

Let Wj(t) be independent standard Brownian motions for $0 \le t \le T$, j = 1, 2, ..., m.

Basic model:
$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sum_{j=1}^m \sigma_{A,i,j}\left(W_j(T) - W_j(t)\right)\right\},$$

where

Let Wj(t) be independent standard Brownian motions for $0 \le t \le T$, j = 1, 2, ..., m.

Basic model:
$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sum_{j=1}^m \sigma_{A,i,j}\left(W_j(T) - W_j(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}^2 = \sum_{j=1}^m \sigma_{A,i,j}^2$ is the volatility, and $\sigma_{A,i,j}$ quantifies the impact of the *j*th Brownian motion on the asset value of firm *i*.

Let Wj(t) be independent standard Brownian motions for $0 \le t \le T$, j = 1, 2, ..., m.

Basic model:
$$V_{A,i}(T) = V_{A,i}(t) \exp\left\{\left(\mu_{A,i} - \frac{\sigma_{A,i}^2}{2}\right)(T-t) + \sum_{j=1}^m \sigma_{A,i,j}\left(W_j(T) - W_j(t)\right)\right\},$$

where

 $\mu_{A,i}$ is the drift, $\sigma_{A,i}^2 = \sum_{j=1}^m \sigma_{A,i,j}^2$ is the volatility, and $\sigma_{A,i,j}$ quantifies the impact of the *j*th Brownian motion on the asset value of firm *i*. Set $Y_i := \frac{\sum_{j=1}^m \sigma_{A,i,j}(W_j(T) - W_j(t))}{\sigma_{A,i}\sqrt{T-t}}$. Then $Y = (Y_1, Y_2, \dots, Y_n) \sim N(0, \Sigma)$,

Difficulties:

- n is typically quite large
- relatively few historical data available
- if n is large, then the pairwise estimated correlations coefficients do not build a positive correlation matrix, in general.

Difficulties:

- n is typically quite large
- relatively few historical data available
- if n is large, then the pairwise estimated correlations coefficients do not build a positive correlation matrix, in general.

Possible approach:

Factor model for the latent variables in which the asset value of a company depends on certain common factors (macro-economical, global, regional, sector-based or country-based factors) and a company specific factor.

Difficulties:

- n is typically quite large
- relatively few historical data available
- if n is large, then the pairwise estimated correlations coefficients do not build a positive correlation matrix, in general.

Possible approach:

Factor model for the latent variables in which the asset value of a company depends on certain common factors (macro-economical, global, regional, sector-based or country-based factors) and a company specific factor.

 $Y = (Y_1, Y_2, \dots, Y_n)^T = AZ + BU$ where

 $Z = (Z_1, \ldots, Z_k)^T \sim N_k(0, \Lambda)$ are the k common factors, $U = (U_1, \ldots, U_n)^T \sim N_n(0, I)$ are the company specific factors such that Z and U are independent, and the constant matrices $A = (a_{ij}) \in \mathbb{R}^{n \times k}$, $B = diag(b_1, \ldots, b_n) \in \mathbb{R}^{n \times n}$ are model parameters.

Difficulties:

- n is typically quite large
- relatively few historical data available
- if n is large, then the pairwise estimated correlations coefficients do not build a positive correlation matrix, in general.

Possible approach:

Factor model for the latent variables in which the asset value of a company depends on certain common factors (macro-economical, global, regional, sector-based or country-based factors) and a company specific factor.

 $Y = (Y_1, Y_2, \dots, Y_n)^T = AZ + BU$ where

 $Z = (Z_1, \ldots, Z_k)^T \sim N_k(0, \Lambda)$ are the k common factors, $U = (U_1, \ldots, U_n)^T \sim N_n(0, I)$ are the company specific factors such that Z and U are independent, and the constant matrices $A = (a_{ij}) \in \mathbb{R}^{n \times k}$, $B = diag(b_1, \ldots, b_n) \in \mathbb{R}^{n \times n}$ are model parameters.

Then we have $cov(Y) = A\Lambda A^T + D$ where $D = diag(b_1^2, \dots, b_n^2) \in \mathbb{R}^{n \times n}$.

Recovery rates

In case of default the recovery rate depends on the status category of the defaulting debtor (prior to default). The mean and the standard deviation of the recovery rate are computed based on the historical data observed over time within each state category.

<ロト (個) (目) (目) (目) (0) (0)</p>

Example: Consider a BBB bond with maturity 5 years, a nominal value of 100 units and a coupon of 6% each year.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

The forward *forward yield curves* for each status category are given as follows (in %):

Status	Year 1	Year 2	Year 3	Year 4
AAA	3.60	4.17	4.73	5.12
AA	3.65	4.22	4.78	5.17
А	3.73	4.32	4.93	5.32

CCC	15.05	15.02	14.03	13.52

Example: Consider a BBB bond with maturity 5 years, a nominal value of 100 units and a coupon of 6% each year.

The forward *forward yield curves* for each status category are given as follows (in %):

Status	Year 1	Year 2	Year 3	Year 4
AAA	3.60	4.17	4.73	5.12
AA	3.65	4.22	4.78	5.17
А	3.73	4.32	4.93	5.32
BBB	4.10	4.67	5.25	5.63
BB	6.05	7.02	8.03	8.52
CCC	15.05	15.02	14.03	13.52

The bond pays 6 units at the end of the 4 years 1, 2, 3, 4 and 106 unit at the end of year 5.

Example: Consider a BBB bond with maturity 5 years, a nominal value of 100 units and a coupon of 6% each year.

The forward *forward yield curves* for each status category are given as follows (in %):

Status	Year 1	Year 2	Year 3	Year 4
AAA	3.60	4.17	4.73	5.12
AA	3.65	4.22	4.78	5.17
А	3.73	4.32	4.93	5.32
BBB	4.10	4.67	5.25	5.63
BB	6.05	7.02	8.03	8.52
CCC	15.05	15.02	14.03	13.52

The bond pays 6 units at the end of the 4 years 1, 2, 3, 4 and 106 unit at the end of year 5.

Assumption: At the end of the first year the bond is rated as an A bond. The value at the end of the first year:

$$V = 6 + \frac{6}{1+3,73\%} + \frac{6}{(1+4,32\%)^2} + \frac{6}{(1+4,93\%)^3} + \frac{106}{(1+5,32\%)^4} = 108.64$$

Example (contd.)

Analogous evaluation of the bond for other status category changes.

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Example (contd.)

Analogous evaluation of the bond for other status category changes.

Assumption: recovery rate in case of default is 51.13%.

Example (contd.)

Analogous evaluation of the bond for other status category changes.

Assumption: recovery rate in case of default is 51.13%.

Status category at the end of the first year	value
AAA	109.35
AA	109.17
А	108.64
BBB	107.53
BB	102.01
В	98.09
CCC	83.63
Default	51.13

Use the transition probabilities of the Markov chain (estimated in terms of historical data) to compute the expected value of the bond at the end of the first year.

The return of bond *i* is modelled by a normal distribution Y_i .

The return of bond *i* is modelled by a normal distribution Y_i .

Let d_{Def} , d_{CCC} , ..., $d_{AAA} = +\infty$ be thresholds which define the transitions probabilities of debtor i at the end of the current period as follows:

 $P(S_i = 0) = \phi(d_{Def}), P(S_i = CCC) = \phi(d_{CCC}) - \phi(d_{Def}), \dots,$ $P(S_i = AAA) = 1 - \phi(AA).$

The return of bond *i* is modelled by a normal distribution Y_i .

Let d_{Def} , d_{CCC} , ..., $d_{AAA} = +\infty$ be thresholds which define the transitions probabilities of debtor i at the end of the current period as follows:

$$P(S_i = 0) = \phi(d_{Def}), P(S_i = CCC) = \phi(d_{CCC}) - \phi(d_{Def}), \dots,$$

$$P(S_i = AAA) = 1 - \phi(AA).$$

The return of a vector of bonds is modelled as a multivariate normal distribution with correlation matrix R estimated by means of factor models.

The return of bond *i* is modelled by a normal distribution Y_i .

Let d_{Def} , d_{CCC} , ..., $d_{AAA} = +\infty$ be thresholds which define the transitions probabilities of debtor i at the end of the current period as follows:

$$P(S_i = 0) = \phi(d_{Def}), P(S_i = CCC) = \phi(d_{CCC}) - \phi(d_{Def}), \dots, P(S_i = AAA) = 1 - \phi(AA).$$

The return of a vector of bonds is modelled as a multivariate normal distribution with correlation matrix R estimated by means of factor models.

Joint probabilities of status category changes, e.g.

$$P(S_1 = 0, \ldots, S_n = 3) = P(Y_1 \le d_{Def}, \ldots, d_B < Y_n \le d_{BB})$$

can be then computed by using the Gaussian copula $C_{n,R}^{Ga}$ of (Y_1, Y_2, \ldots, Y_n) .

The return of bond *i* is modelled by a normal distribution Y_i .

Let d_{Def} , d_{CCC} , ..., $d_{AAA} = +\infty$ be thresholds which define the transitions probabilities of debtor i at the end of the current period as follows:

$$P(S_i = 0) = \phi(d_{Def}), P(S_i = CCC) = \phi(d_{CCC}) - \phi(d_{Def}), \dots,$$

$$P(S_i = AAA) = 1 - \phi(AA).$$

The return of a vector of bonds is modelled as a multivariate normal distribution with correlation matrix R estimated by means of factor models.

Joint probabilities of status category changes, e.g.

$$P(S_1 = 0, \dots, S_n = 3) = P(Y_1 \leq d_{Def}, \dots, d_B < Y_n \leq d_{BB})$$

can be then computed by using the Gaussian copula $C_{n,R}^{Ga}$ of (Y_1, Y_2, \ldots, Y_n) .

Use simulation to compute the risk measures (VaR, CVaR) of the bond portfolio, e.g. by generating a large number of scenarios and then computing the empirical estimators of VaR, CVaR.

Then $E(\lambda_i(Z)) = \bar{\lambda}_i > 0$) holds.

The density function of Z_j is given as $f_j(z) = \frac{z^{\alpha_j - 1} \exp\{-z/\beta_j\}}{\beta_j^{\alpha_j} \Gamma(\alpha_j)}$

The loss given default for debtor *i* is $LGD_i = (1 - \lambda_i)L_i$, $1 \le i \le n$, where λ_i is the expected deterministic recovery rate and L_i is the amount of credit *i*.

(developed by CSFB in 1997, see Crouhy et al. (2000) and www.credit_suisse.com/investment_banking/research/en/credit_risk.jsp

Consider *m* independent risik factors $Z_1, Z_2, \ldots, Z_m, Z_j \sim \Gamma(\alpha_j, \beta_j)$, $j = 1, 2, \ldots, m$, with parameter α_j , β_j generally choosen such that such that $E(Z_j) = 1$.

Let $\lambda_i(Z) = \overline{\lambda}_i \sum_{j=1}^m a_{ij}Z_j$, $\sum_{j=1}^m a_{ij} = 1$ for i = 1, 2, ..., n for some parameters $\overline{\lambda}_i > 0$. Then $E(\lambda_i(Z)) = \overline{\lambda}_i > 0$ holds.

The density function of Z_j is given as $f_j(z) = \frac{z^{\alpha_j - 1} \exp\{-z/\beta_j\}}{\beta_j^{\alpha_j} \Gamma(\alpha_j)}$

The loss given default for debtor *i* is $LGD_i = (1 - \lambda_i)L_i$, $1 \le i \le n$, where λ_i is the expected deterministic recovery rate and L_i is the amount of credit *i*.

The goal: approximate the loss disribution by a discrete distribution durch and derive the generator function for the latter.

The loss will be approximated as an integer multiple of a prespecified loss unit L_0 (e.g. $L_o = 10^6$ Euro):

The loss will be approximated as an integer multiple of a prespecified loss unit L_0 (e.g. $L_o = 10^6$ Euro):

$$\begin{split} LGD_i &= (1 - \lambda_i)L_i \approx \left[\frac{(1 - \lambda_i)L_i}{L_0}\right]L_0 = v_iL_0 \text{ with } v_i := \left[\frac{(1 - \lambda_i)L_i}{L_0}\right],\\ \text{where } [x] &= \arg\min_t\{|t - x| \colon t \in \mathbb{Z}, t - x \in (-1/2, 1/2]\}. \end{split}$$

The loss will be approximated as an integer multiple of a prespecified loss unit L_0 (e.g. $L_o = 10^6$ Euro):

$$\begin{split} LGD_i &= (1 - \lambda_i)L_i \approx \left[\frac{(1 - \lambda_i)L_i}{L_0}\right]L_0 = v_iL_0 \text{ with } v_i := \left[\frac{(1 - \lambda_i)L_i}{L_0}\right],\\ \text{where } [x] &= \arg\min_t\{|t - x| \colon t \in \mathbb{Z}, t - x \in (-1/2, 1/2]\}. \end{split}$$

The loss function is then given by $L = \sum_{i=1}^{n} \bar{X}_i v_i L_0 \approx \sum_{i=1}^{n} X_i v_i L_0$, where \bar{X}_i is the loss indicator and (X_1, \ldots, X_n) has a PMD with factor vector (Z_1, Z_2, \ldots, Z_m) as described above.

The loss will be approximated as an integer multiple of a prespecified loss unit L_0 (e.g. $L_o = 10^6$ Euro):

$$LGD_i = (1 - \lambda_i)L_i \approx \left[\frac{(1 - \lambda_i)L_i}{L_0}\right]L_0 = v_iL_0 \text{ with } v_i := \left[\frac{(1 - \lambda_i)L_i}{L_0}\right],$$

where $[x] = \arg\min_t\{|t - x|: t \in \mathbb{Z}, t - x \in (-1/2, 1/2]\}.$

The loss function is then given by $L = \sum_{i=1}^{n} \bar{X}_i v_i L_0 \approx \sum_{i=1}^{n} X_i v_i L_0$, where \bar{X}_i is the loss indicator and (X_1, \ldots, X_n) has a PMD with factor vector (Z_1, Z_2, \ldots, Z_m) as described above.

Step 1 Determine the pgf of (the approximative) number of losses $N = X_1 + \ldots + X_n$

The loss will be approximated as an integer multiple of a prespecified loss unit L_0 (e.g. $L_o = 10^6$ Euro):

$$LGD_i = (1 - \lambda_i)L_i \approx \left[\frac{(1 - \lambda_i)L_i}{L_0}\right]L_0 = v_iL_0 \text{ with } v_i := \left[\frac{(1 - \lambda_i)L_i}{L_0}\right],$$

where $[x] = \arg\min_t\{|t - x|: t \in \mathbb{Z}, t - x \in (-1/2, 1/2]\}.$

The loss function is then given by $L = \sum_{i=1}^{n} \bar{X}_i v_i L_0 \approx \sum_{i=1}^{n} X_i v_i L_0$, where \bar{X}_i is the loss indicator and (X_1, \ldots, X_n) has a PMD with factor vector (Z_1, Z_2, \ldots, Z_m) as described above.

Step 1 Determine the pgf of (the approximative) number of losses $N = X_1 + \ldots + X_n$

 $\begin{aligned} X_i|Z \sim Poi(\lambda_i(Z)), \ \forall i \Longrightarrow g_{X_i|Z}(t) &= \exp\{\lambda_i(Z)(t-1)\}, \ \forall i \Longrightarrow \\ g_{N|Z}(t) &= \prod_{i=1}^n g_{X_i|Z}(t) = \prod_{i=1}^n \exp\{\lambda_i(Z)(t-1)\} = \exp\{\mu(t-1)\}, \\ \text{with } \mu &:= \sum_{i=1}^n \lambda_i(Z) = \sum_{i=1}^n \left(\bar{\lambda}_i \sum_{j=1}^m a_{ij} Z_j\right). \end{aligned}$

The computation of each integral in the product obove yields

Then

$$g_N(t) = \int_0^\infty \dots \int_0^\infty g_{N|Z=(z_1, z_2, \dots, z_m)} f_1(z_1) \dots f_m(z_m) dz_1 \dots dz_m =$$

$$\int_0^\infty \dots \int_0^\infty \exp\left\{\sum_{i=1}^n \left(\bar{\lambda}_i \sum_{j=1}^m a_{ij} z_j\right)(t-1)\right\} f_1(z_1) \dots f_m(z_m) dz_1 \dots dz_m =$$

$$\int_0^\infty \dots \int_0^\infty \exp\left\{(t-1) \sum_{j=1}^m \left(\sum_{i=1}^n \bar{\lambda}_i a_{ij}\right) z_j\right)\right\} f_1(z_1) \dots f_m(z_m) dz_1 \dots dz_m =$$

$$\int_{0}^{\infty} \dots \int_{0}^{\infty} \exp\{(t-1)\mu_{1}z_{1}\}f_{1}(z_{1})dz_{1}\dots\exp\{(t-1)\mu_{m}z_{m}\}f_{m}(z_{m})dz_{m} = \prod_{j=1}^{m} \int_{0}^{\infty} \exp\{z_{j}\mu_{j}(t-1)\}\frac{1}{\beta_{j}^{\alpha_{j}}\Gamma(\alpha_{j})}z_{j}^{\alpha_{j}-1}\exp\{-z_{j}/\beta_{j}\}dz_{j}$$

The computation of each integral in the product obove yields

$$\int_{0}^{\infty} \frac{1}{\Gamma(\alpha_{j})\beta_{j}^{\alpha_{j}}} \exp\{z_{j}\mu_{j}(t-1)\}z_{j}^{\alpha_{j}-1} \exp\{-z_{j}/\beta_{j}\}dz_{j} = \left(\frac{1-\delta_{j}}{1-\delta_{j}t}\right)^{\alpha_{j}} \text{ with } \delta_{j} = \beta_{j}\mu_{j}/(1+\beta_{j}\mu_{j}).$$

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(\frac{1-\delta_j}{1-\delta_j t}\right)^{\alpha_j}$$
.

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(\frac{1-\delta_j}{1-\delta_j t}\right)^{\alpha_j}$$
.

Step 2 Determine the pgf of the (approximated) loss distribution $L = \sum_{i=1}^{n} X_i v_i L_0.$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(\frac{1-\delta_j}{1-\delta_j t}\right)^{\alpha_j}$$
.

Step 2 Determine the pgf of the (approximated) loss distribution $L = \sum_{i=1}^{n} X_i v_i L_0.$

The conditional loss due to default of debtor *i* is $L_i|Z = v_i(X_i|Z)$

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(rac{1-\delta_j}{1-\delta_j t}
ight)^{lpha_j}$$

Step 2 Determine the pgf of the (approximated) loss distribution $L = \sum_{i=1}^{n} X_i v_i L_0.$

The conditional loss due to default of debtor *i* is $L_i|Z = v_i(X_i|Z)$ $L_i|Z$ are independent for $i = 1, 2, ..., n \Longrightarrow$ $g_{L_i|Z}(t) = E(t^{L_i}|Z) = E(t^{v_iX_i}|Z) = g_{X_i|Z}(t^{v_i}) = \exp\{\lambda_i(Z)(t^{v_i}-1)\}.$

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(\frac{1-\delta_j}{1-\delta_j t}
ight)^{lpha_j}$$

Step 2 Determine the pgf of the (approximated) loss distribution $L = \sum_{i=1}^{n} X_i v_i L_0.$

The conditional loss due to default of debtor *i* is $L_i|Z = v_i(X_i|Z)$ $L_i|Z$ are independent for $i = 1, 2, ..., n \Longrightarrow$ $g_{L_i|Z}(t) = E(t^{L_i}|Z) = E(t^{v_iX_i}|Z) = g_{X_i|Z}(t^{v_i}) = \exp\{\lambda_i(Z)(t^{v_i}-1)\}.$ The pgf od the conditional overall loss is $g_{L|Z}(t) = g_{L_1+L_2+...+L_n|Z}(t) = \prod_{i=1}^n g_{L_i|Z}(t) =$ $\prod_{i=1}^n g_{X_i|Z}(t^{v_i}) = \exp\{\sum_{j=1}^m Z_j(\sum_{i=1}^n \overline{\lambda}_i a_{ij}(t^{v_i}-1))\}.$

Thus we have
$$g_N(t) = \prod_{j=1}^m \left(rac{1-\delta_j}{1-\delta_j t}
ight)^{lpha_j}$$

Step 2 Determine the pgf of the (approximated) loss distribution $L = \sum_{i=1}^{n} X_i v_i L_0.$

The conditional loss due to default of debtor *i* is $L_i|Z = v_i(X_i|Z)$ $L_i|Z$ are independent for $i = 1, 2, ..., n \Longrightarrow$ $g_{L_i|Z}(t) = E(t^{L_i}|Z) = E(t^{v_iX_i}|Z) = g_{X_i|Z}(t^{v_i}) = \exp\{\lambda_i(Z)(t^{v_i}-1)\}.$ The pgf od the conditional overall loss is $g_{L|Z}(t) = g_{L_1+L_2+...+L_n|Z}(t) = \prod_{i=1}^n g_{L_i|Z}(t) =$ $\prod_{i=1}^n g_{X_i|Z}(t^{v_i}) = \exp\left\{\sum_{j=1}^m Z_j\left(\sum_{i=1}^n \overline{\lambda}_i a_{ij}(t^{v_j}-1)\right)\right\}.$

Analogous computations as in the case of $g_N(t)$ yield:

$$g_L(t) = \prod_{j=1}^m \left(rac{1-\delta_j}{1-\delta_j\Lambda_j(t)}
ight)^{lpha_j} ext{ wobei } \Lambda_j(t) = rac{1}{\mu_j}\sum_{i=1}^n ar\lambda_i a_{ij}t^{v_i}.$$

Let *P* be a credit portfolio consisting of *m* credits. The loss function is $L = \sum_{i=1}^{m} L_i$ and the single credit losses L_i are independent conditioned on a vector *Z* of economical impact factors.

Goal: Determine $VaR_{\alpha}(L) = q_{\alpha}(L)$, $CVaR_{\alpha} = E(L|L > q_{\alpha}(L))$, $CVaR_{i,\alpha} = E(L_i|L > q_{\alpha}(L))$, for all *i*.

Let P be a credit portfolio consisting of m credits.

The loss function is $L = \sum_{i=1}^{m} L_i$ and the single credit losses L_i are independent conditioned on a vector Z of economical impact factors.

Goal: Determine $VaR_{\alpha}(L) = q_{\alpha}(L)$, $CVaR_{\alpha} = E(L|L > q_{\alpha}(L))$, $CVaR_{i,\alpha} = E(L_i|L > q_{\alpha}(L))$, for all *i*.

Application of Monte Carlo (MC) simulation has to deal with the simulation of rare events!

E.g. for $\alpha = 0,99$ only 1% of the standard MC simulations will lead to a loss L, such that $L > q_{\alpha}(L)$.

Let P be a credit portfolio consisting of m credits.

The loss function is $L = \sum_{i=1}^{m} L_i$ and the single credit losses L_i are independent conditioned on a vector Z of economical impact factors.

Goal: Determine $VaR_{\alpha}(L) = q_{\alpha}(L)$, $CVaR_{\alpha} = E(L|L > q_{\alpha}(L))$, $CVaR_{i,\alpha} = E(L_i|L > q_{\alpha}(L))$, for all *i*.

Application of Monte Carlo (MC) simulation has to deal with the simulation of rare events!

E.g. for $\alpha = 0,99$ only 1% of the standard MC simulations will lead to a loss L, such that $L > q_{\alpha}(L)$.

The standard MC estimator is:

$$\widehat{CVaR}_{\alpha}^{(MC)}(L) = \frac{1}{\sum_{i=1}^{n} I_{(q_{\alpha},+\infty)}(L^{(i)})} \sum_{i=1}^{n} L^{(i)} I_{(q_{\alpha},+\infty)}(L^{(i)}),$$

where L_i is the value of the loss in the *i*th simulation run.
Monte Carlo methods in credit risk management

Let P be a credit portfolio consisting of m credits.

The loss function is $L = \sum_{i=1}^{m} L_i$ and the single credit losses L_i are independent conditioned on a vector Z of economical impact factors.

Goal: Determine $VaR_{\alpha}(L) = q_{\alpha}(L)$, $CVaR_{\alpha} = E(L|L > q_{\alpha}(L))$, $CVaR_{i,\alpha} = E(L_i|L > q_{\alpha}(L))$, for all *i*.

Application of Monte Carlo (MC) simulation has to deal with the simulation of rare events!

E.g. for $\alpha = 0,99$ only 1% of the standard MC simulations will lead to a loss L, such that $L > q_{\alpha}(L)$.

The standard MC estimator is:

$$\widehat{CVaR}_{\alpha}^{(MC)}(L) = \frac{1}{\sum_{i=1}^{n} I_{(q_{\alpha},+\infty)}(L^{(i)})} \sum_{i=1}^{n} L^{(i)} I_{(q_{\alpha},+\infty)}(L^{(i)}),$$

where L_i is the value of the loss in the *i*th simulation run.

 $\widehat{CVaR}_{\alpha}^{(MC)}(L)$ is unstable, i.e. it has a very high variance, if the number of simulation runs ist not very high.

Let f and g be probability densities. Define probability measures P and Q:

$$P(A) := \int_{x \in A} f(x) dx$$
 and $Q(A) := \int_{x \in A} g(x) dx$ for $A \subset \mathbb{R}$.

Goal: Estimate the expected value $\theta := E^P(h(X))$ of a given function $h: \mathcal{F} \to \mathbb{R}$ in the probability space (Ω, \mathcal{F}, P) .

We have $\theta := E^P(h(X)) = E^Q(h(X)r(X))$ with r(x) := dP/dQ, thus r is the density of P w.r.t. Q.

Exponential tilting in the case of probability measures: Let X be a r.v. in (Ω, \mathcal{F}, P) such that $M_X(t) = E^P(\exp\{tX\}) < \infty$, $\forall t$. Define a probability measure Q_t in (Ω, \mathcal{F}) , such that $dQ_t/dP = \exp(tX)/M_X(t)$, i.e. $Q_t(A) := E^P\left(\frac{\exp\{tX\}}{M_X(t)}; A\right)$. We have $\frac{dP}{dQ_t} = M_X(t)\exp(-tX) =: r_t(X)$. The IS algorithm does not change: Simulate independent realisations of

 X_i in $(\Omega, \mathcal{F}, Q_t)$ and set $\hat{\theta}_n^{(IS)} = (1/n) \sum_{i=1}^n X_i r_t(X_i)$.

IS in the case of Bernoulli mixture models

(see Glasserman and Li (2003))

Consider the loss function of a credit portfolio $L = \sum_{i=1}^{m} e_i Y_i$.
(see Glasserman and Li (2003))

Consider the loss function of a credit portfolio $L = \sum_{i=1}^{m} e_i Y_i$.

 Y_i are the loss indicators with default probability \bar{p}_i and $e_i = (1 - \lambda_i)L_i$ are the positive deterministic exposures in the case that a corresponding loss happens. λ_i are the recovery rates and L_i are the credit nominals, for i = 1, 2, ..., m.

(see Glasserman and Li (2003))

Consider the loss function of a credit portfolio $L = \sum_{i=1}^{m} e_i Y_i$.

 Y_i are the loss indicators with default probability \bar{p}_i and $e_i = (1 - \lambda_i)L_i$ are the positive deterministic exposures in the case that a corresponding loss happens. λ_i are the recovery rates and L_i are the credit nominals, for i = 1, 2, ..., m.

Let Z be a vector of economical impact factors, such that $Y_i|Z$ are independent and $Y_i|(Z = z) \sim Bernoulli(p_i(z))$, $\forall i = 1, 2, ..., m$.

(see Glasserman and Li (2003))

Consider the loss function of a credit portfolio $L = \sum_{i=1}^{m} e_i Y_i$.

 Y_i are the loss indicators with default probability \bar{p}_i and $e_i = (1 - \lambda_i)L_i$ are the positive deterministic exposures in the case that a corresponding loss happens. λ_i are the recovery rates and L_i are the credit nominals, for i = 1, 2, ..., m.

Let Z be a vector of economical impact factors, such that $Y_i|Z$ are independent and $Y_i|(Z = z) \sim Bernoulli(p_i(z)), \forall i = 1, 2, ..., m$.

Goal: Estimation of $\theta = P(L \ge c)$ by means of IS, for some given c with c >> E(L).

(see Glasserman and Li (2003))

Consider the loss function of a credit portfolio $L = \sum_{i=1}^{m} e_i Y_i$.

 Y_i are the loss indicators with default probability \bar{p}_i and $e_i = (1 - \lambda_i)L_i$ are the positive deterministic exposures in the case that a corresponding loss happens. λ_i are the recovery rates and L_i are the credit nominals, for i = 1, 2, ..., m.

Let Z be a vector of economical impact factors, such that $Y_i|Z$ are independent and $Y_i|(Z = z) \sim Bernoulli(p_i(z))$, $\forall i = 1, 2, ..., m$.

Goal: Estimation of $\theta = P(L \ge c)$ by means of IS, for some given c with c >> E(L).

Simplified case: Y_i are independent for i = 1, 2, ..., m. Let $\Omega = \{0, 1\}^m$ be the state space of the random vector Y. Consider the probability measure P in Ω :

$$P(\{y\}) = \prod_{i=1}^{m} ar{p}_{i}^{y_{i}} (1 - ar{p}_{i})^{1 - y_{i}}, \ y \in \{0, 1\}^{m}.$$

The moment generating function of L is $M_L(t) = \prod_{i=1}^m (e^{te_i}\bar{p}_i + 1 - \bar{p}_i)$.

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1 - y_i} \right).$$

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1-y_i} \right).$$

Let $\bar{q}_{t,i}$ be new default probabilities

$$\bar{q}_{t,i} := \exp\{te_i\}\bar{p}_i/(\exp\{te_i\}\bar{p}_i+1-\bar{p}_i).$$

◆□▶ ◆□▶ ◆臣▶ ◆臣▶ 臣 のへぐ

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1 - y_i} \right).$$

Let $\bar{q}_{t,i}$ be new default probabilities

$$ar{q}_{t,i} := \exp\{te_i\}ar{p}_i/(\exp\{te_i\}ar{p}_i+1-ar{p}_i).$$

(日) (日) (日) (日) (日) (日) (日) (日)

We have $Q_t(\{y\}) = \prod_{i=1}^m \bar{q}_i^{y_i} (1 - \bar{q}_i)^{1-y_i}$, for $y \in \{0, 1\}^m$.

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1 - y_i} \right).$$

Let $\bar{q}_{t,i}$ be new default probabilities

$$ar{q}_{t,i} := \exp\{te_i\}ar{p}_i/(\exp\{te_i\}ar{p}_i+1-ar{p}_i).$$

We have $Q_t(\{y\}) = \prod_{i=1}^m \bar{q}_i^{y_i} (1 - \bar{q}_i)^{1-y_i}$, for $y \in \{0, 1\}^m$.

Thus after applying the exponential tilting the default indicators are independent with new default probabilities $\bar{q}_{t,i}$.

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1 - y_i} \right).$$

Let $\bar{q}_{t,i}$ be new default probabilities

$$ar{q}_{t,i} := \exp\{te_i\}ar{p}_i/(\exp\{te_i\}ar{p}_i+1-ar{p}_i).$$

We have $Q_t(\{y\}) = \prod_{i=1}^m \bar{q}_i^{y_i} (1 - \bar{q}_i)^{1-y_i}$, for $y \in \{0, 1\}^m$.

Thus after applying the exponential tilting the default indicators are independent with new default probabilities $\bar{q}_{t,i}$.

 $\lim_{t\to\infty} \bar{q}_{t,i} = 1$ and $\lim_{t\to-\infty} \bar{q}_{t,i} = 0$ imply that $E^{Q_t}(L)$ takes all values in $(0, \sum_{i=1}^m e_i)$ for $t \in \mathbb{R}$.

$$Q_t(\{y\}) = \prod_{i=1}^n \left(\frac{\exp\{te_i y_i\}}{\exp\{te_i\}\bar{p}_i + 1 - \bar{p}_i} \bar{p}_i^{y_i} (1 - \bar{p}_i)^{1 - y_i} \right).$$

Let $\bar{q}_{t,i}$ be new default probabilities

$$ar{q}_{t,i} := \exp\{te_i\}ar{p}_i/(\exp\{te_i\}ar{p}_i+1-ar{p}_i).$$

We have $Q_t(\{y\}) = \prod_{i=1}^m \bar{q}_i^{y_i} (1 - \bar{q}_i)^{1-y_i}$, for $y \in \{0, 1\}^m$.

Thus after applying the exponential tilting the default indicators are independent with new default probabilities $\bar{q}_{t,i}$.

 $\lim_{t\to\infty} \bar{q}_{t,i} = 1 \text{ and } \lim_{t\to-\infty} \bar{q}_{t,i} = 0 \text{ imply that } E^{Q_t}(L) \text{ takes all values in } (0, \sum_{i=1}^m e_i) \text{ for } t \in \mathbb{R}.$ Choose *t*, such that $\sum_{i=1}^m e_i \bar{q}_{t,i} = c$.

The general case: Y_i are independent conditional on Z

The general case: Y_i are independent conditional on Z

1. Step: Estimation of the conditional excess probabilites $\theta(z) := P(L \ge c | Z = z)$ for a given realisation z of the economic factor Z, by means of the IS approach for the simplified case.

< □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > < □ > <

The general case: Y_i are independent conditional on Z

1. Step: Estimation of the conditional excess probabilites $\theta(z) := P(L \ge c | Z = z)$ for a given realisation z of the economic factor Z, by means of the IS approach for the simplified case.

Algorithm: IS for the conditional loss distribution

(1) For a given z compute the conditional default probabilities $p_i(z)$ (as in the simplified case) and solve the equation

$$\sum_{i=1}^{m} e_i \frac{\exp\{te_i\}p_i(z)}{\exp\{te_i\}p_i(z)+1-p_i(z)} = c \,.$$

The solution t = t(c, z) specifies the correct *degree of tilting*.

The general case: Y_i are independent conditional on Z

1. Step: Estimation of the conditional excess probabilites $\theta(z) := P(L \ge c | Z = z)$ for a given realisation z of the economic factor Z, by means of the IS approach for the simplified case.

Algorithm: IS for the conditional loss distribution

(1) For a given z compute the conditional default probabilities $p_i(z)$ (as in the simplified case) and solve the equation

$$\sum_{i=1}^{m} e_i \frac{\exp\{te_i\}p_i(z)}{\exp\{te_i\}p_i(z) + 1 - p_i(z)} = c \,.$$

The solution t = t(c, z) specifies the correct *degree of tilting*.

(2) Generate n₁ conditional realisations of the vector of default indicators (Y₁,..., Y_m), Y_i are simulated from Bernoulli(q_i), i = 1, 2, ..., m, with

$$q_i = \frac{\exp\{t(c, z)e_i\}p_i(z)}{\exp\{t(c, z)e_i\}p_i(z) + 1 - p_i(z)}$$

(3) Let M_L(t, z) := ∏[exp{t(c, z)e_i}p_i(z) + 1 - p_i(z)] be the conditional moment generating function of L. Let L⁽¹⁾, L⁽²⁾,...,L^(n₁) be the n₁ conditional realisations of L for the n₁ simulated realisations of Y₁, Y₂,...,Y_m. Compute the *IS*-estimator for the tail probability of the conditional loss distribution:

$$\hat{\theta}_{n_1}^{(IS)}(z) = M_L(t(c,z),z) \frac{1}{n_1} \sum_{j=1}^{n_1} I_{L^{(j)} \ge c} \exp\{-t(c,z)L^{(j)}\} L^{(j)}.$$

(3) Let M_L(t, z) := ∏[exp{t(c, z)e_i}p_i(z) + 1 - p_i(z)] be the conditional moment generating function of L. Let L⁽¹⁾, L⁽²⁾,...,L^(n₁) be the n₁ conditional realisations of L for the n₁ simulated realisations of Y₁, Y₂,..., Y_m. Compute the *IS*-estimator for the tail probability of the conditional loss distribution:

$$\hat{\theta}_{n_1}^{(IS)}(z) = M_L(t(c,z),z) \frac{1}{n_1} \sum_{j=1}^{n_1} I_{L^{(j)} \ge c} \exp\{-t(c,z) L^{(j)}\} L^{(j)}.$$

2. Step: Estimation of the unconditional excess probability $\theta = P(L \ge c)$.

(3) Let M_L(t, z) := ∏[exp{t(c, z)e_i}p_i(z) + 1 - p_i(z)] be the conditional moment generating function of L. Let L⁽¹⁾, L⁽²⁾,...,L^(n₁) be the n₁ conditional realisations of L for the n₁ simulated realisations of Y₁, Y₂,..., Y_m. Compute the *IS*-estimator for the tail probability of the conditional loss distribution:

$$\hat{\theta}_{n_1}^{(IS)}(z) = M_L(t(c,z),z) \frac{1}{n_1} \sum_{j=1}^{n_1} I_{L^{(j)} \ge c} \exp\{-t(c,z)L^{(j)}\} L^{(j)}.$$

2. Step: Estimation of the unconditional excess probability $\theta = P(L \ge c)$.

Naive approach: Generate many realisations z of the impact factors Z and compute $\hat{\theta}_{n_1}^{(IS)}(z)$ for every one of them. The required estimator is the average of $\hat{\theta}_{n_1}^{(IS)}(z)$ over all realisations z. This is not the most efficient approach, see Glasserman and Li (2003).

(3) Let M_L(t, z) := ∏[exp{t(c, z)e_i}p_i(z) + 1 - p_i(z)] be the conditional moment generating function of L. Let L⁽¹⁾, L⁽²⁾,...,L^(n₁) be the n₁ conditional realisations of L for the n₁ simulated realisations of Y₁, Y₂,..., Y_m. Compute the *IS*-estimator for the tail probability of the conditional loss distribution:

$$\hat{\theta}_{n_1}^{(IS)}(z) = M_L(t(c,z),z) \frac{1}{n_1} \sum_{j=1}^{n_1} I_{L^{(j)} \ge c} \exp\{-t(c,z)L^{(j)}\} L^{(j)}.$$

2. Step: Estimation of the unconditional excess probability $\theta = P(L \ge c)$.

Naive approach: Generate many realisations z of the impact factors Z and compute $\hat{\theta}_{n_1}^{(IS)}(z)$ for every one of them. The required estimator is the average of $\hat{\theta}_{n_1}^{(IS)}(z)$ over all realisations z. This is not the most efficient approach, see Glasserman and Li (2003). A better alternative: IS for the impact factors.

Assumption: $Z \sim N_{\rho}(0, \Sigma)$ (e.g. probit-normal Bernoulli mixture)

Assumption: $Z \sim N_p(0, \Sigma)$ (e.g. probit-normal Bernoulli mixture) Let the IS density g be the density of $N_p(\mu, \Sigma)$ for a new expected vector $\mu \in \mathbb{R}^p$. A good choice of μ should lead to frequent realisations of z which imply high conditional default probabilities $p_i(z)$.

$$r_{\mu}(Z) = \frac{\exp\{-\frac{1}{2}Z^{t}\Sigma^{-1}Z\}}{\exp\{-\frac{1}{2}(Z-\mu)^{t}\Sigma^{-1}(Z-\mu)\}} = \exp\{-\mu^{t}\Sigma^{-1}Z + \frac{1}{2}\mu^{t}\Sigma^{1}\mu\}$$

Algorithm: complete IS for Bernoulli mixture models with Gaussian factors

- (1) Generate $z_1, z_2, ..., z_n \sim N_p(\mu, \Sigma)$ (*n* is the number of the simulation rounds)
- (2) For each z_i compute $\hat{\theta}_{n_1}^{(IS)}(z_i)$ by applying the IS algorithm for the conditional loss.

Assumption: $Z \sim N_p(0, \Sigma)$ (e.g. probit-normal Bernoulli mixture) Let the IS density g be the density of $N_p(\mu, \Sigma)$ for a new expected vector $\mu \in \mathbb{R}^p$. A good choice of μ should lead to frequent realisations of z which imply high conditional default probabilities $p_i(z)$.

The likelihood ratio:

$$r_{\mu}(Z) = \frac{\exp\{-\frac{1}{2}Z^{t}\Sigma^{-1}Z\}}{\exp\{-\frac{1}{2}(Z-\mu)^{t}\Sigma^{-1}(Z-\mu)\}} = \exp\{-\mu^{t}\Sigma^{-1}Z + \frac{1}{2}\mu^{t}\Sigma^{1}\mu\}$$

Algorithm: complete IS for Bernoulli mixture models with Gaussian factors

- (1) Generate $z_1, z_2, ..., z_n \sim N_p(\mu, \Sigma)$ (*n* is the number of the simulation rounds)
- (2) For each z_i compute $\hat{\theta}_{n_1}^{(IS)}(z_i)$ by applying the IS algorithm for the conditional loss.
- (3) compute the IS estimator for the independent excess probability:

$$\hat{\theta}_{n}^{(IS)} = \frac{1}{n} \sum_{i=1}^{n} r_{\mu}(z_{i}) \hat{\theta}_{n_{1}}^{(IS)}(z_{i})$$

<□ > < @ > < E > < E > E のQ @

 $\boldsymbol{\mu}$ should be chosen such that the variance of the estimator is small.

◆□ ▶ < 圖 ▶ < 圖 ▶ < 圖 ▶ < 圖 • 의 Q @</p>

 μ should be chosen such that the variance of the estimator is small. A sketch of the idea of Glasserman and Li (2003):

 μ should be chosen such that the variance of the estimator is small.

A sketch of the idea of Glasserman and Li (2003):

Since $\hat{\theta}_{n_1}^{(IS)}(z) \approx P(L \ge c | Z = z)$, search for an appropriate IS density for the function $z \mapsto P(L \ge c | Z = z)$.

 μ should be chosen such that the variance of the estimator is small.

A sketch of the idea of Glasserman and Li (2003):

Since $\hat{\theta}_{n_1}^{(IS)}(z) \approx P(L \ge c | Z = z)$, search for an appropriate IS density for the function $z \mapsto P(L \ge c | Z = z)$.

Approach:

a) the optimal IS density g^* is proportional to $P(L \ge c | Z = z) \exp\{-\frac{1}{2}z^t \Sigma^{-1}z\}.$

 μ should be chosen such that the variance of the estimator is small.

A sketch of the idea of Glasserman and Li (2003):

Since $\hat{\theta}_{n_1}^{(IS)}(z) \approx P(L \ge c | Z = z)$, search for an appropriate IS density for the function $z \mapsto P(L \ge c | Z = z)$.

Approach:

a) the optimal IS density g^* is proportional to $P(L \ge c | Z = z) \exp\{-\frac{1}{2}z^t \Sigma^{-1}z\}.$

b) use as IS density a multivariate normal distribution with the same mode as the optimal IS density g^* .

 $\boldsymbol{\mu}$ should be chosen such that the variance of the estimator is small.

A sketch of the idea of Glasserman and Li (2003):

Since $\hat{\theta}_{n_1}^{(IS)}(z) \approx P(L \ge c | Z = z)$, search for an appropriate IS density for the function $z \mapsto P(L \ge c | Z = z)$.

Approach:

a) the optimal IS density g^* is proportional to $P(L \ge c | Z = z) \exp\{-\frac{1}{2}z^t \Sigma^{-1}z\}.$

b) use as IS density a multivariate normal distribution with the same mode as the optimal IS density g^* .

The mode of a multivariate normal distribution $N_p(\mu, \Sigma)$ equals the expected vector μ , thus determining μ leads to the following optimization problem:

$$\mu = \operatorname{argmax}_{z} \left\{ P(L \ge c | Z = z) \exp\{-\frac{1}{2}z^{t}\Sigma^{-1}z\} \right\}.$$

 μ should be chosen such that the variance of the estimator is small.

The mode of a multivariate normal distribution $N_p(\mu, \Sigma)$ equals the expected vector μ , thus determining μ leads to the following optimization problem:

$$\mu = \operatorname{argmax}_{z} \left\{ P(L \ge c | Z = z) \exp\{-\frac{1}{2}z^{t}\Sigma^{-1}z\} \right\}.$$

This problem is hard to solve exactly; in general $P(L \ge c | Z = z)$ is not available in analytical form.

 μ should be chosen such that the variance of the estimator is small.
